A landslide-prone area has deposits that can slide down an inclined surface. These deposits may be made up of impermeable layers or granular deposits on slopes greater than 15%, known as landslides. The presence of impermeable soil (Criterion B.2) is inferred from analyzing a ground-surface digital elevation model, created from MF-1543, and the Geologic Map of the Bothell Quadrangle, USGS.

Locations of existing landslides (Criterion A) have been compiled for the Bothell planning area, which includes both historical and currently active landslides. Any area with a combination of these criteria is considered to be at risk of landslide activity.

The City of Bothell delivers this data (map) in as-is condition. GIS data (maps) are produced by the City of Bothell for internal purposes. No guarantee is made concerning the accuracy, currency, or completeness of the information provided.
